Preface

ELF: Executable and Linking Format

The Executable and Linking Format was originally developed and published by UNIX System Laboratories (USL) as part of the Application Binary Interface (ABI). The Tool Interface Standards committee (TIS) has selected the evolving ELF standard as a portable object file format that works on 32-bit Intel Architecture environments for a variety of operating systems.

The ELF standard is intended to streamline software development by providing developers with a set of binary interface definitions that extend across multiple operating environments. This should reduce the number of different interface implementations, thereby reducing the need for recoding and recompiling code.

About This Document

This document is intended for developers who are creating object or executable files on various 32-bit environment operating systems. It is divided into the following three parts:

- Part 1, “Object Files” describes the ELF object file format for the three main types of object files.
- Part 2, “Program Loading and Dynamic Linking” describes the object file information and system actions that create running programs.
- Part 3, “C Library” lists the symbols contained in `libsys`, the standard ANSI C and `libc` routines, and the global data symbols required by the `libc` routines.

NOTE

References to X86 architecture have been changed to Intel Architecture.

Introduction

Part 1 describes the iABI object file format, called ELF (Executable and Linking Format). There are three main types of object files.

- A *relocatable file* holds code and data suitable for linking with other object files to create an executable or a shared object file.
- An *executable file* holds a program suitable for execution; the file specifies how `exec(BA_OS)` creates a program's process image.
- A *shared object file* holds code and data suitable for linking in two contexts. First, the link editor [see `ld(SD_CMD)`] may process it with other relocatable and shared object files to create another object file. Second, the dynamic linker combines it with an executable file and other shared objects to create a process image.

Created by the assembler and link editor, object files are binary representations of programs intended to execute directly on a processor. Programs that require other abstract machines, such as shell scripts, are excluded.

After the introductory material, Part 1 focuses on the file format and how it pertains to building programs. Part 2 also describes parts of the object file, concentrating on the information necessary to execute a program.

File Format

Object files participate in program linking (building a program) and program execution (running a program). For convenience and efficiency, the object file format provides parallel views of a file's contents, reflecting the differing needs of these activities. Figure 1-1 shows an object file's organization.

Figure 1-1: Object File Format

Linking View	Execution View
ELF header	ELF header
Program header table <i>optional</i>	Program header table
Section 1	Segment 1
...	
Section <i>n</i>	Segment 2
...	
...	...
Section header table	Section header table <i>optional</i>

An *ELF header* resides at the beginning and holds a “road map” describing the file's organization. *Sections* hold the bulk of object file information for the linking view: instructions, data, symbol table, relocation information, and so on. Descriptions of special sections appear later in Part 1. Part 2 discusses *segments* and the program execution view of the file.

A *program header table*, if present, tells the system how to create a process image. Files used to build a process image (execute a program) must have a program header table; relocatable files do not need one. A *section header table* contains information describing the file’s sections. Every section has an entry in the table; each entry gives information such as the section name, the section size, etc. Files used during linking must have a section header table; other object files may or may not have one.

NOTE

Although the figure shows the program header table immediately after the ELF header, and the section header table following the sections, actual files may differ. Moreover, sections and segments have no specified order. Only the ELF header has a fixed position in the file.

Data Representation

As described here, the object file *format* supports various processors with 8-bit bytes and 32-bit architectures. Nevertheless, it is intended to be extensible to larger (or smaller) architectures. Object files therefore represent some control data with a machine-independent format, making it possible to identify object files and interpret their contents in a common way. Remaining data in an object file use the encoding of the target processor, regardless of the machine on which the file was created.

Figure 1-2: 32-Bit Data Types

Name	Size	Alignment	Purpose
Elf32_Addr	4	4	Unsigned program address
Elf32_Half	2	2	Unsigned medium integer
Elf32_Off	4	4	Unsigned file offset
Elf32_Sword	4	4	Signed large integer
Elf32_Word	4	4	Unsigned large integer
unsigned char	1	1	Unsigned small integer

All data structures that the object file format defines follow the “natural” size and alignment guidelines for the relevant class. If necessary, data structures contain explicit padding to ensure 4-byte alignment for 4-byte objects, to force structure sizes to a multiple of 4, etc. Data also have suitable alignment from the beginning of the file. Thus, for example, a structure containing an `Elf32_Addr` member will be aligned on a 4-byte boundary within the file.

For portability reasons, ELF uses no bit-fields.

ELF Header

Some object file control structures can grow, because the ELF header contains their actual sizes. If the object file format changes, a program may encounter control structures that are larger or smaller than expected. Programs might therefore ignore “extra” information. The treatment of “missing” information depends on context and will be specified when and if extensions are defined.

Figure 1-3: ELF Header

```
#define EI_NIDENT      16

typedef struct {
    unsigned char    e_ident[EI_NIDENT];
    Elf32_Half       e_type;
    Elf32_Half       e_machine;
    Elf32_Word       e_version;
    Elf32_Addr       e_entry;
    Elf32_Off        e_phoff;
    Elf32_Off        e_shoff;
    Elf32_Word       e_flags;
    Elf32_Half       e_ehsize;
    Elf32_Half       e_phentsize;
    Elf32_Half       e_phnum;
    Elf32_Half       e_shentsize;
    Elf32_Half       e_shnum;
    Elf32_Half       e_shstrndx;
} Elf32_Ehdr;
```

e_ident The initial bytes mark the file as an object file and provide machine-independent data with which to decode and interpret the file’s contents. Complete descriptions appear below, in “ELF Identification.”

e_type This member identifies the object file type.

Name	Value	Meaning
ET_NONE	0	No file type
ET_REL	1	Relocatable file
ET_EXEC	2	Executable file
ET_DYN	3	Shared object file
ET_CORE	4	Core file
ET_LOPROC	0xff00	Processor-specific
ET_HIPROC	0xffff	Processor-specific

Although the core file contents are unspecified, type ET_CORE is reserved to mark the file. Values from ET_LOPROC through ET_HIPROC (inclusive) are reserved for processor-specific semantics. Other values are reserved and will be assigned to new object file types as necessary.

e_machine This member's value specifies the required architecture for an individual file.

Name	Value	Meaning
EM_NONE	0	No machine
EM_M32	1	AT&T WE 32100
EM_SPARC	2	SPARC
EM_386	3	Intel 80386
EM_68K	4	Motorola 68000
EM_88K	5	Motorola 88000
EM_860	7	Intel 80860
EM_MIPS	8	MIPS RS3000

Other values are reserved and will be assigned to new machines as necessary. Processor-specific ELF names use the machine name to distinguish them. For example, the flags mentioned below use the prefix `EF_`; a flag named `WIDGET` for the `EM_XYZ` machine would be called `EF_XYZ_WIDGET`.

e_version This member identifies the object file version.

Name	Value	Meaning
EV_NONE	0	Invalid version
EV_CURRENT	1	Current version

The value 1 signifies the original file format; extensions will create new versions with higher numbers. The value of `EV_CURRENT`, though given as 1 above, will change as necessary to reflect the current version number.

e_entry This member gives the virtual address to which the system first transfers control, thus starting the process. If the file has no associated entry point, this member holds zero.

e_phoff This member holds the program header table's file offset in bytes. If the file has no program header table, this member holds zero.

e_shoff This member holds the section header table's file offset in bytes. If the file has no section header table, this member holds zero.

e_flags This member holds processor-specific flags associated with the file. Flag names take the form `EF_machine_flag`. See "Machine Information" for flag definitions.

e_ehsize This member holds the ELF header's size in bytes.

e_phentsize This member holds the size in bytes of one entry in the file's program header table; all entries are the same size.

e_phnum This member holds the number of entries in the program header table. Thus the product of `e_phentsize` and `e_phnum` gives the table's size in bytes. If a file has no program header table, `e_phnum` holds the value zero.

e_shentsize This member holds a section header's size in bytes. A section header is one entry in the section header table; all entries are the same size.

e_shnum This member holds the number of entries in the section header table. Thus the product of `e_shentsize` and `e_shnum` gives the section header table's size in bytes. If a file has no section header table, `e_shnum` holds the value zero.

e_shstrndx This member holds the section header table index of the entry associated with the section name string table. If the file has no section name string table, this member holds the value SHN_UNDEF. See “Sections” and “String Table” below for more information.

ELF Identification

As mentioned above, ELF provides an object file framework to support multiple processors, multiple data encodings, and multiple classes of machines. To support this object file family, the initial bytes of the file specify how to interpret the file, independent of the processor on which the inquiry is made and independent of the file’s remaining contents.

The initial bytes of an ELF header (and an object file) correspond to the **e_ident** member.

Figure 1-4: e_ident[] Identification Indexes

Name	Value	Purpose
EI_MAG0	0	File identification
EI_MAG1	1	File identification
EI_MAG2	2	File identification
EI_MAG3	3	File identification
EI_CLASS	4	File class
EI_DATA	5	Data encoding
EI_VERSION	6	File version
EI_PAD	7	Start of padding bytes
EI_NIDENT	16	Size of e_ident[]

These indexes access bytes that hold the following values.

EI_MAG0 to EI_MAG3

A file’s first 4 bytes hold a “magic number,” identifying the file as an ELF object file.

Name	Value	Position
ELFMAG0	0x7f	e_ident[EI_MAG0]
ELFMAG1	‘E’	e_ident[EI_MAG1]
ELFMAG2	‘L’	e_ident[EI_MAG2]
ELFMAG3	‘F’	e_ident[EI_MAG3]

EI_CLASS The next byte, **e_ident[EI_CLASS]**, identifies the file’s class, or capacity.

Name	Value	Meaning
ELFCLASSNONE	0	Invalid class
ELFCLASS32	1	32-bit objects
ELFCLASS64	2	64-bit objects

The file format is designed to be portable among machines of various sizes, without imposing the sizes of the largest machine on the smallest. Class `ELFCLASS32` supports machines with files and virtual address spaces up to 4 gigabytes; it uses the basic types defined above.

Class `ELFCLASS64` is reserved for 64-bit architectures. Its appearance here shows how the object file may change, but the 64-bit format is otherwise unspecified. Other classes will be defined as necessary, with different basic types and sizes for object file data.

`EI_DATA` Byte `e_ident[EI_DATA]` specifies the data encoding of the processor-specific data in the object file. The following encodings are currently defined.

Name	Value	Meaning
ELFDATANONE	0	Invalid data encoding
ELFDATA2LSB	1	See below
ELFDATA2MSB	2	See below

More information on these encodings appears below. Other values are reserved and will be assigned to new encodings as necessary.

`EI_VERSION` Byte `e_ident[EI_VERSION]` specifies the ELF header version number. Currently, this value must be `EV_CURRENT`, as explained above for `e_version`.

`EI_PAD` This value marks the beginning of the unused bytes in `e_ident`. These bytes are reserved and set to zero; programs that read object files should ignore them. The value of `EI_PAD` will change in the future if currently unused bytes are given meanings.

A file’s data encoding specifies how to interpret the basic objects in a file. As described above, class `ELFCLASS32` files use objects that occupy 1, 2, and 4 bytes. Under the defined encodings, objects are represented as shown below. Byte numbers appear in the upper left corners.

Encoding `ELFDATA2LSB` specifies 2’s complement values, with the least significant byte occupying the lowest address.

Figure 1-5: Data Encoding `ELFDATA2LSB`

Encoding `ELFDATA2MSB` specifies 2's complement values, with the most significant byte occupying the lowest address.

Figure 1-6: Data Encoding `ELFDATA2MSB`

Machine Information

For file identification in `e_ident`, the 32-bit Intel Architecture requires the following values.

Figure 1-7: 32-bit Intel Architecture Identification, `e_ident`

Position	Value
<code>e_ident[EI_CLASS]</code>	<code>ELFCLASS32</code>
<code>e_ident[EI_DATA]</code>	<code>ELFDATA2LSB</code>

Processor identification resides in the ELF header's `e_machine` member and must have the value `EM_386`.

The ELF header's `e_flags` member holds bit flags associated with the file. The 32-bit Intel Architecture defines no flags; so this member contains zero.

Sections

An object file’s section header table lets one locate all the file’s sections. The section header table is an array of `Elf32_Shdr` structures as described below. A section header table index is a subscript into this array. The ELF header’s `e_shoff` member gives the byte offset from the beginning of the file to the section header table; `e_shnum` tells how many entries the section header table contains; `e_shentsize` gives the size in bytes of each entry.

Some section header table indexes are reserved; an object file will not have sections for these special indexes.

Figure 1-8: Special Section Indexes

Name	Value
SHN_UNDEF	0
SHN_LORESERVE	0xfff00
SHN_LOPROC	0xff00
SHN_HIPROC	0xff1f
SHN_ABS	0xffff1
SHN_COMMON	0xffff2
SHN_HIRESERVE	0xfffff

SHN_UNDEF This value marks an undefined, missing, irrelevant, or otherwise meaningless section reference. For example, a symbol “defined” relative to section number `SHN_UNDEF` is an undefined symbol.

NOTE

Although index 0 is reserved as the undefined value, the section header table contains an entry for index 0. That is, if the `e_shnum` member of the ELF header says a file has 6 entries in the section header table, they have the indexes 0 through 5. The contents of the initial entry are specified later in this section.

- SHN_LORESERVE** This value specifies the lower bound of the range of reserved indexes.
- SHN_LOPROC through SHN_HIPROC** Values in this inclusive range are reserved for processor-specific semantics.
- SHN_ABS** This value specifies absolute values for the corresponding reference. For example, symbols defined relative to section number `SHN_ABS` have absolute values and are not affected by relocation.
- SHN_COMMON** Symbols defined relative to this section are common symbols, such as FORTRAN COMMON or unallocated C external variables.
- SHN_HIRESERVE** This value specifies the upper bound of the range of reserved indexes. The system reserves indexes between `SHN_LORESERVE` and `SHN_HIRESERVE`, inclusive; the values do not reference the section header table. That is, the section header table does *not* contain entries for the reserved indexes.

Sections contain all information in an object file, except the ELF header, the program header table, and the section header table. Moreover, object files’ sections satisfy several conditions.

- Every section in an object file has exactly one section header describing it. Section headers may exist that do not have a section.
- Each section occupies one contiguous (possibly empty) sequence of bytes within a file.
- Sections in a file may not overlap. No byte in a file resides in more than one section.
- An object file may have inactive space. The various headers and the sections might not “cover” every byte in an object file. The contents of the inactive data are unspecified.

A section header has the following structure.

Figure 1-9: Section Header

```
typedef struct {
    Elf32_Word      sh_name;
    Elf32_Word      sh_type;
    Elf32_Word      sh_flags;
    Elf32_Addr      sh_addr;
    Elf32_Off       sh_offset;
    Elf32_Word      sh_size;
    Elf32_Word      sh_link;
    Elf32_Word      sh_info;
    Elf32_Word      sh_addralign;
    Elf32_Word      sh_entsize;
} Elf32_Shdr;
```

<code>sh_name</code>	This member specifies the name of the section. Its value is an index into the section header string table section [see “String Table” below], giving the location of a null-terminated string.
<code>sh_type</code>	This member categorizes the section’s contents and semantics. Section types and their descriptions appear below.
<code>sh_flags</code>	Sections support 1-bit flags that describe miscellaneous attributes. Flag definitions appear below.
<code>sh_addr</code>	If the section will appear in the memory image of a process, this member gives the address at which the section’s first byte should reside. Otherwise, the member contains 0.
<code>sh_offset</code>	This member’s value gives the byte offset from the beginning of the file to the first byte in the section. One section type, <code>SHT_NOBITS</code> described below, occupies no space in the file, and its <code>sh_offset</code> member locates the conceptual placement in the file.
<code>sh_size</code>	This member gives the section’s size in bytes. Unless the section type is <code>SHT_NOBITS</code> , the section occupies <code>sh_size</code> bytes in the file. A section of type <code>SHT_NOBITS</code> may have a non-zero size, but it occupies no space in the file.
<code>sh_link</code>	This member holds a section header table index link, whose interpretation depends on the section type. A table below describes the values.

sh_info	This member holds extra information, whose interpretation depends on the section type. A table below describes the values.
sh_addralign	Some sections have address alignment constraints. For example, if a section holds a doubleword, the system must ensure doubleword alignment for the entire section. That is, the value of sh_addr must be congruent to 0, modulo the value of sh_addralign. Currently, only 0 and positive integral powers of two are allowed. Values 0 and 1 mean the section has no alignment constraints.
sh_entsize	Some sections hold a table of fixed-size entries, such as a symbol table. For such a section, this member gives the size in bytes of each entry. The member contains 0 if the section does not hold a table of fixed-size entries.

A section header’s sh_type member specifies the section’s semantics.

Figure 1-10: Section Types, sh_type

Name	Value
SHT_NULL	0
SHT_PROGBITS	1
SHT_SYMTAB	2
SHT_STRTAB	3
SHT_RELA	4
SHT_HASH	5
SHT_DYNAMIC	6
SHT_NOTE	7
SHT_NOBITS	8
SHT_REL	9
SHT_SHLIB	10
SHT_DYNSYM	11
SHT_LOPROC	0x70000000
SHT_HIPROC	0x7fffffff
SHT_LOUSER	0x80000000
SHT_HIUSER	0xffffffff

SHT_NULL	This value marks the section header as inactive; it does not have an associated section. Other members of the section header have undefined values.
SHT_PROGBITS	The section holds information defined by the program, whose format and meaning are determined solely by the program.
SHT_SYMTAB and SHT_DYNSYM	These sections hold a symbol table. Currently, an object file may have only one section of each type, but this restriction may be relaxed in the future. Typically, SHT_SYMTAB provides symbols for link editing, though it may also be used for dynamic linking. As a complete symbol table, it may contain many symbols unnecessary for dynamic linking. Consequently, an object file may also contain a SHT_DYNSYM section, which holds a minimal set of dynamic linking symbols, to save space. See “Symbol Table” below for details.

SHT_STRTAB	The section holds a string table. An object file may have multiple string table sections. See “String Table” below for details.
SHT_RELA	The section holds relocation entries with explicit addends, such as type <code>Elf32_Rela</code> for the 32-bit class of object files. An object file may have multiple relocation sections. See “Relocation” below for details.
SHT_HASH	The section holds a symbol hash table. All objects participating in dynamic linking must contain a symbol hash table. Currently, an object file may have only one hash table, but this restriction may be relaxed in the future. See “Hash Table” in Part 2 for details.
SHT_DYNAMIC	The section holds information for dynamic linking. Currently, an object file may have only one dynamic section, but this restriction may be relaxed in the future. See “Dynamic Section” in Part 2 for details.
SHT_NOTE	The section holds information that marks the file in some way. See “Note Section” in Part 2 for details.
SHT_NOBITS	A section of this type occupies no space in the file but otherwise resembles <code>SHT_PROGBITS</code> . Although this section contains no bytes, the <code>sh_offset</code> member contains the conceptual file offset.
SHT_REL	The section holds relocation entries without explicit addends, such as type <code>Elf32_Rel</code> for the 32-bit class of object files. An object file may have multiple relocation sections. See “Relocation” below for details.
SHT_SHLIB	This section type is reserved but has unspecified semantics. Programs that contain a section of this type do not conform to the ABI.
SHT_LOPROC through SHT_HIPROC	Values in this inclusive range are reserved for processor-specific semantics.
SHT_LOUSER	This value specifies the lower bound of the range of indexes reserved for application programs.
SHT_HIUSER	This value specifies the upper bound of the range of indexes reserved for application programs. Section types between <code>SHT_LOUSER</code> and <code>SHT_HIUSER</code> may be used by the application, without conflicting with current or future system-defined section types.

Other section type values are reserved. As mentioned before, the section header for index 0 (`SHN_UNDEF`) exists, even though the index marks undefined section references. This entry holds the following.

Figure 1-11: Section Header Table Entry: Index 0

Name	Value	Note
<code>sh_name</code>	0	No name
<code>sh_type</code>	<code>SHT_NULL</code>	Inactive
<code>sh_flags</code>	0	No flags
<code>sh_addr</code>	0	No address
<code>sh_offset</code>	0	No file offset
<code>sh_size</code>	0	No size

Figure 1-11: Section Header Table Entry: Index 0 (continued)

sh_link	SHN_UNDEF	No link information
sh_info	0	No auxiliary information
sh_addralign	0	No alignment
sh_entsize	0	No entries

A section header’s `sh_flags` member holds 1-bit flags that describe the section’s attributes. Defined values appear below; other values are reserved.

Figure 1-12: Section Attribute Flags, `sh_flags`

Name	Value
SHF_WRITE	0x1
SHF_ALLOC	0x2
SHF_EXECINSTR	0x4
SHF_MASKPROC	0xf0000000

If a flag bit is set in `sh_flags`, the attribute is “on” for the section. Otherwise, the attribute is “off” or does not apply. Undefined attributes are set to zero.

- SHF_WRITE The section contains data that should be writable during process execution.
- SHF_ALLOC The section occupies memory during process execution. Some control sections do not reside in the memory image of an object file; this attribute is off for those sections.
- SHF_EXECINSTR The section contains executable machine instructions.
- SHF_MASKPROC All bits included in this mask are reserved for processor-specific semantics.

Two members in the section header, `sh_link` and `sh_info`, hold special information, depending on section type.

Figure 1-13: sh_link and sh_info Interpretation

sh_type	sh_link	sh_info
SHT_DYNAMIC	The section header index of the string table used by entries in the section.	0
SHT_HASH	The section header index of the symbol table to which the hash table applies.	0
SHT_REL SHT_RELA	The section header index of the associated symbol table.	The section header index of the section to which the relocation applies.
SHT_SYMTAB SHT_DYNSYM	The section header index of the associated string table.	One greater than the symbol table index of the last local symbol (binding STB_LOCAL).
other	SHN_UNDEF	0

Special Sections

Various sections hold program and control information. Sections in the list below are used by the system and have the indicated types and attributes.

Figure 1-14: Special Sections

Name	Type	Attributes
.bss	SHT_NOBITS	SHF_ALLOC + SHF_WRITE
.comment	SHT_PROGBITS	none
.data	SHT_PROGBITS	SHF_ALLOC + SHF_WRITE
.data1	SHT_PROGBITS	SHF_ALLOC + SHF_WRITE
.debug	SHT_PROGBITS	none
.dynamic	SHT_DYNAMIC	see below
.dynstr	SHT_STRTAB	SHF_ALLOC
.dysym	SHT_DYNSYM	SHF_ALLOC
.fini	SHT_PROGBITS	SHF_ALLOC + SHF_EXECINSTR
.got	SHT_PROGBITS	see below
.hash	SHT_HASH	SHF_ALLOC
.init	SHT_PROGBITS	SHF_ALLOC + SHF_EXECINSTR
.interp	SHT_PROGBITS	see below
.line	SHT_PROGBITS	none
.note	SHT_NOTE	none
.plt	SHT_PROGBITS	see below
.relname	SHT_REL	see below

Figure 1-14: Special Sections (continued)

<code>.relaname</code>	SHT_REL	see below
<code>.rodata</code>	SHT_PROGBITS	SHF_ALLOC
<code>.rodata1</code>	SHT_PROGBITS	SHF_ALLOC
<code>.shstrtab</code>	SHT_STRTAB	none
<code>.strtab</code>	SHT_STRTAB	see below
<code>.symtab</code>	SHT_SYMTAB	see below
<code>.text</code>	SHT_PROGBITS	SHF_ALLOC + SHF_EXECINSTR

<code>.bss</code>	This section holds uninitialized data that contribute to the program's memory image. By definition, the system initializes the data with zeros when the program begins to run. The section occupies no file space, as indicated by the section type, SHT_NOBITS.
<code>.comment</code>	This section holds version control information.
<code>.data</code> and <code>.data1</code>	These sections hold initialized data that contribute to the program's memory image.
<code>.debug</code>	This section holds information for symbolic debugging. The contents are unspecified.
<code>.dynamic</code>	This section holds dynamic linking information. The section's attributes will include the SHF_ALLOC bit. Whether the SHF_WRITE bit is set is processor specific. See Part 2 for more information.
<code>.dynstr</code>	This section holds strings needed for dynamic linking, most commonly the strings that represent the names associated with symbol table entries. See Part 2 for more information.
<code>.dynsym</code>	This section holds the dynamic linking symbol table, as "Symbol Table" describes. See Part 2 for more information.
<code>.fini</code>	This section holds executable instructions that contribute to the process termination code. That is, when a program exits normally, the system arranges to execute the code in this section.
<code>.got</code>	This section holds the global offset table. See "Special Sections" in Part 1 and "Global Offset Table" in Part 2 for more information.
<code>.hash</code>	This section holds a symbol hash table. See "Hash Table" in Part 2 for more information.
<code>.init</code>	This section holds executable instructions that contribute to the process initialization code. That is, when a program starts to run, the system arranges to execute the code in this section before calling the main program entry point (called <code>main</code> for C programs).
<code>.interp</code>	This section holds the path name of a program interpreter. If the file has a loadable segment that includes the section, the section's attributes will include the SHF_ALLOC bit; otherwise, that bit will be off. See Part 2 for more information.
<code>.line</code>	This section holds line number information for symbolic debugging, which describes the correspondence between the source program and the machine code. The contents are unspecified.

- `.note` This section holds information in the format that “Note Section” in Part 2 describes.
- `.plt` This section holds the procedure linkage table. See “Special Sections” in Part 1 and “Procedure Linkage Table” in Part 2 for more information.
- `.relname` and `.relaname`
 These sections hold relocation information, as “Relocation” below describes. If the file has a loadable segment that includes relocation, the sections’ attributes will include the `SHF_ALLOC` bit; otherwise, that bit will be off. Conventionally, *name* is supplied by the section to which the relocations apply. Thus a relocation section for `.text` normally would have the name `.rel.text` or `.rela.text`.
- `.rodata` and `.rodata1`
 These sections hold read-only data that typically contribute to a non-writable segment in the process image. See “Program Header” in Part 2 for more information.
- `.shstrtab` This section holds section names.
- `.strtab` This section holds strings, most commonly the strings that represent the names associated with symbol table entries. If the file has a loadable segment that includes the symbol string table, the section’s attributes will include the `SHF_ALLOC` bit; otherwise, that bit will be off.
- `.symtab` This section holds a symbol table, as “Symbol Table” in this section describes. If the file has a loadable segment that includes the symbol table, the section’s attributes will include the `SHF_ALLOC` bit; otherwise, that bit will be off.
- `.text` This section holds the “text,” or executable instructions, of a program.

Section names with a dot (.) prefix are reserved for the system, although applications may use these sections if their existing meanings are satisfactory. Applications may use names without the prefix to avoid conflicts with system sections. The object file format lets one define sections not in the list above. An object file may have more than one section with the same name.

Section names reserved for a processor architecture are formed by placing an abbreviation of the architecture name ahead of the section name. The name should be taken from the architecture names used for `e_machine`. For instance `.FOO.psect` is the `psect` section defined by the `FOO` architecture. Existing extensions are called by their historical names.

<code>.gptab</code>	<code>.liblist</code>
<code>.conflict</code>	

String Table

String table sections hold null-terminated character sequences, commonly called strings. The object file uses these strings to represent symbol and section names. One references a string as an index into the string table section. The first byte, which is index zero, is defined to hold a null character. Likewise, a string table's last byte is defined to hold a null character, ensuring null termination for all strings. A string whose index is zero specifies either no name or a null name, depending on the context. An empty string table section is permitted; its section header's `sh_size` member would contain zero. Non-zero indexes are invalid for an empty string table.

A section header's `sh_name` member holds an index into the section header string table section, as designated by the `e_shstrndx` member of the ELF header. The following figures show a string table with 25 bytes and the strings associated with various indexes.

Index	+0	+1	+2	+3	+4	+5	+6	+7	+8	+9
0	\0	n	a	m	e	.	\0	v	a	r
10	i	a	b	l	e	\0	a	b	l	e
20	\0	\0	x	x	\0					

Figure 1-15: String Table Indexes

Index	String
0	<i>none</i>
1	name.
7	Variable
11	able
16	able
24	<i>null string</i>

As the example shows, a string table index may refer to any byte in the section. A string may appear more than once; references to substrings may exist; and a single string may be referenced multiple times. Unreferenced strings also are allowed.

Symbol Table

An object file's symbol table holds information needed to locate and relocate a program's symbolic definitions and references. A symbol table index is a subscript into this array. Index 0 both designates the first entry in the table and serves as the undefined symbol index. The contents of the initial entry are specified later in this section.

Name	Value
STN_UNDEF	0

A symbol table entry has the following format.

Figure 1-16: Symbol Table Entry

```
typedef struct {
    Elf32_Word    st_name;
    Elf32_Addr    st_value;
    Elf32_Word    st_size;
    unsigned char st_info;
    unsigned char st_other;
    Elf32_Half    st_shndx;
} Elf32_Sym;
```

st_name This member holds an index into the object file's symbol string table, which holds the character representations of the symbol names. If the value is non-zero, it represents a string table index that gives the symbol name. Otherwise, the symbol table entry has no name.

NOTE

External C symbols have the same names in C and object files' symbol tables.

st_value This member gives the value of the associated symbol. Depending on the context, this may be an absolute value, an address, etc.; details appear below.

st_size Many symbols have associated sizes. For example, a data object's size is the number of bytes contained in the object. This member holds 0 if the symbol has no size or an unknown size.

st_info This member specifies the symbol's type and binding attributes. A list of the values and meanings appears below. The following code shows how to manipulate the values.

```
#define ELF32_ST_BIND(i) ((i)>>4)
#define ELF32_ST_TYPE(i) ((i)&0xf)
#define ELF32_ST_INFO(b,t) (((b)<<4)+((t)&0xf))
```

- `st_other` This member currently holds 0 and has no defined meaning.
- `st_shndx` Every symbol table entry is “defined” in relation to some section; this member holds the relevant section header table index. As Figure 1-7 and the related text describe, some section indexes indicate special meanings.

A symbol’s binding determines the linkage visibility and behavior.

Figure 1-17: Symbol Binding, `ELF32_ST_BIND`

Name	Value
<code>STB_LOCAL</code>	0
<code>STB_GLOBAL</code>	1
<code>STB_WEAK</code>	2
<code>STB_LOPROC</code>	13
<code>STB_HIPROC</code>	15

- `STB_LOCAL` Local symbols are not visible outside the object file containing their definition. Local symbols of the same name may exist in multiple files without interfering with each other.
- `STB_GLOBAL` Global symbols are visible to all object files being combined. One file’s definition of a global symbol will satisfy another file’s undefined reference to the same global symbol.
- `STB_WEAK` Weak symbols resemble global symbols, but their definitions have lower precedence.
- `STB_LOPROC` through `STB_HIPROC` Values in this inclusive range are reserved for processor-specific semantics.

Global and weak symbols differ in two major ways.

- When the link editor combines several relocatable object files, it does not allow multiple definitions of `STB_GLOBAL` symbols with the same name. On the other hand, if a defined global symbol exists, the appearance of a weak symbol with the same name will not cause an error. The link editor honors the global definition and ignores the weak ones. Similarly, if a common symbol exists (i.e., a symbol whose `st_shndx` field holds `SHN_COMMON`), the appearance of a weak symbol with the same name will not cause an error. The link editor honors the common definition and ignores the weak ones.
- When the link editor searches archive libraries, it extracts archive members that contain definitions of undefined global symbols. The member’s definition may be either a global or a weak symbol. The link editor does *not* extract archive members to resolve undefined weak symbols. Unresolved weak symbols have a zero value.

In each symbol table, all symbols with `STB_LOCAL` binding precede the weak and global symbols. As “Sections” above describes, a symbol table section’s `sh_info` section header member holds the symbol table index for the first non-local symbol.

A symbol's type provides a general classification for the associated entity.

Figure 1-18: Symbol Types, ELF32_ST_TYPE

Name	Value
STT_NOTYPE	0
STT_OBJECT	1
STT_FUNC	2
STT_SECTION	3
STT_FILE	4
STT_LOPROC	13
STT_HIPROC	15

STT_NOTYPE	The symbol's type is not specified.
STT_OBJECT	The symbol is associated with a data object, such as a variable, an array, etc.
STT_FUNC	The symbol is associated with a function or other executable code.
STT_SECTION	The symbol is associated with a section. Symbol table entries of this type exist primarily for relocation and normally have STB_LOCAL binding.
STT_FILE	Conventionally, the symbol's name gives the name of the source file associated with the object file. A file symbol has STB_LOCAL binding, its section index is SHN_ABS, and it precedes the other STB_LOCAL symbols for the file, if it is present.
STT_LOPROC through STT_HIPROC	Values in this inclusive range are reserved for processor-specific semantics.

Function symbols (those with type STT_FUNC) in shared object files have special significance. When another object file references a function from a shared object, the link editor automatically creates a procedure linkage table entry for the referenced symbol. Shared object symbols with types other than STT_FUNC will not be referenced automatically through the procedure linkage table.

If a symbol's value refers to a specific location within a section, its section index member, `st_shndx`, holds an index into the section header table. As the section moves during relocation, the symbol's value changes as well, and references to the symbol continue to "point" to the same location in the program. Some special section index values give other semantics.

SHN_ABS	The symbol has an absolute value that will not change because of relocation.
SHN_COMMON	The symbol labels a common block that has not yet been allocated. The symbol's value gives alignment constraints, similar to a section's <code>sh_addralign</code> member. That is, the link editor will allocate the storage for the symbol at an address that is a multiple of <code>st_value</code> . The symbol's size tells how many bytes are required.
SHN_UNDEF	This section table index means the symbol is undefined. When the link editor combines this object file with another that defines the indicated symbol, this file's references to the symbol will be linked to the actual definition.

As mentioned above, the symbol table entry for index 0 (STN_UNDEF) is reserved; it holds the following.

Figure 1-19: Symbol Table Entry: Index 0

Name	Value	Note
st_name	0	No name
st_value	0	Zero value
st_size	0	No size
st_info	0	No type, local binding
st_other	0	
st_shndx	SHN_UNDEF	No section

Symbol Values

Symbol table entries for different object file types have slightly different interpretations for the `st_value` member.

- In relocatable files, `st_value` holds alignment constraints for a symbol whose section index is `SHN_COMMON`.
- In relocatable files, `st_value` holds a section offset for a defined symbol. That is, `st_value` is an offset from the beginning of the section that `st_shndx` identifies.
- In executable and shared object files, `st_value` holds a virtual address. To make these files' symbols more useful for the dynamic linker, the section offset (file interpretation) gives way to a virtual address (memory interpretation) for which the section number is irrelevant.

Although the symbol table values have similar meanings for different object files, the data allow efficient access by the appropriate programs.

Relocation

Relocation is the process of connecting symbolic references with symbolic definitions. For example, when a program calls a function, the associated call instruction must transfer control to the proper destination address at execution. In other words, relocatable files must have information that describes how to modify their section contents, thus allowing executable and shared object files to hold the right information for a process's program image. *Relocation entries* are these data.

Figure 1-20: Relocation Entries

```
typedef struct {
    Elf32_Addr    r_offset;
    Elf32_Word    r_info;
} Elf32_Rel;

typedef struct {
    Elf32_Addr    r_offset;
    Elf32_Word    r_info;
    Elf32_Sword    r_addend;
} Elf32_Rela;
```

r_offset This member gives the location at which to apply the relocation action. For a relocatable file, the value is the byte offset from the beginning of the section to the storage unit affected by the relocation. For an executable file or a shared object, the value is the virtual address of the storage unit affected by the relocation.

r_info This member gives both the symbol table index with respect to which the relocation must be made, and the type of relocation to apply. For example, a call instruction's relocation entry would hold the symbol table index of the function being called. If the index is `STN_UNDEF`, the undefined symbol index, the relocation uses 0 as the "symbol value." Relocation types are processor-specific. When the text refers to a relocation entry's relocation type or symbol table index, it means the result of applying `ELF32_R_TYPE` or `ELF32_R_SYM`, respectively, to the entry's `r_info` member.

```
#define ELF32_R_SYM(i)    ((i)>>8)
#define ELF32_R_TYPE(i)   ((unsigned char)(i))
#define ELF32_R_INFO(s,t) (((s)<<8)+(unsigned char)(t))
```

r_addend This member specifies a constant addend used to compute the value to be stored into the relocatable field.

As shown above, only `Elf32_Rela` entries contain an explicit addend. Entries of type `Elf32_Rel` store an implicit addend in the location to be modified. Depending on the processor architecture, one form or the other might be necessary or more convenient. Consequently, an implementation for a particular machine may use one form exclusively or either form depending on context.

A relocation section references two other sections: a symbol table and a section to modify. The section header's `sh_info` and `sh_link` members, described in "Sections" above, specify these relationships. Relocation entries for different object files have slightly different interpretations for the `r_offset` member.

- In relocatable files, `r_offset` holds a section offset. That is, the relocation section itself describes how to modify another section in the file; relocation offsets designate a storage unit within the second section.
- In executable and shared object files, `r_offset` holds a virtual address. To make these files' relocation entries more useful for the dynamic linker, the section offset (file interpretation) gives way to a virtual address (memory interpretation).

Although the interpretation of `r_offset` changes for different object files to allow efficient access by the relevant programs, the relocation types' meanings stay the same.

Relocation Types

Relocation entries describe how to alter the following instruction and data fields (bit numbers appear in the lower box corners).

Figure 1-21: Relocatable Fields

word32 This specifies a 32-bit field occupying 4 bytes with arbitrary byte alignment. These values use the same byte order as other word values in the 32-bit Intel Architecture.

Calculations below assume the actions are transforming a relocatable file into either an executable or a shared object file. Conceptually, the link editor merges one or more relocatable files to form the output. It first decides how to combine and locate the input files, then updates the symbol values, and finally performs the relocation. Relocations applied to executable or shared object files are similar and accomplish the same result. Descriptions below use the following notation.

- A This means the addend used to compute the value of the relocatable field.
- B This means the base address at which a shared object has been loaded into memory during execution. Generally, a shared object file is built with a 0 base virtual address, but the execution address will be different.

- G** This means the offset into the global offset table at which the address of the relocation entry's symbol will reside during execution. See "Global Offset Table" in Part 2 for more information.
- GOT** This means the address of the global offset table. See "Global Offset Table" in Part 2 for more information.
- L** This means the place (section offset or address) of the procedure linkage table entry for a symbol. A procedure linkage table entry redirects a function call to the proper destination. The link editor builds the initial procedure linkage table, and the dynamic linker modifies the entries during execution. See "Procedure Linkage Table" in Part 2 for more information.
- P** This means the place (section offset or address) of the storage unit being relocated (computed using `r_offset`).
- S** This means the value of the symbol whose index resides in the relocation entry.

A relocation entry's `r_offset` value designates the offset or virtual address of the first byte of the affected storage unit. The relocation type specifies which bits to change and how to calculate their values. The SYSTEM V architecture uses only `Elf32_Rel` relocation entries, the field to be relocated holds the addend. In all cases, the addend and the computed result use the same byte order.

Figure 1-22: Relocation Types

Name	Value	Field	Calculation
<code>R_386_NONE</code>	0	none	none
<code>R_386_32</code>	1	<i>word32</i>	$S + A$
<code>R_386_PC32</code>	2	<i>word32</i>	$S + A - P$
<code>R_386_GOT32</code>	3	<i>word32</i>	$G + A - P$
<code>R_386_PLT32</code>	4	<i>word32</i>	$L + A - P$
<code>R_386_COPY</code>	5	none	none
<code>R_386_GLOB_DAT</code>	6	<i>word32</i>	S
<code>R_386_JMP_SLOT</code>	7	<i>word32</i>	S
<code>R_386_RELATIVE</code>	8	<i>word32</i>	$B + A$
<code>R_386_GOTOFF</code>	9	<i>word32</i>	$S + A - GOT$
<code>R_386_GOTPC</code>	10	<i>word32</i>	$GOT + A - P$

Some relocation types have semantics beyond simple calculation.

- `R_386_GOT32`** This relocation type computes the distance from the base of the global offset table to the symbol's global offset table entry. It additionally instructs the link editor to build a global offset table.
- `R_386_PLT32`** This relocation type computes the address of the symbol's procedure linkage table entry and additionally instructs the link editor to build a procedure linkage table.
- `R_386_COPY`** The link editor creates this relocation type for dynamic linking. Its offset member refers to a location in a writable segment. The symbol table index specifies a symbol that should exist both in the current object file and in a shared object. During execution, the dynamic linker copies data associated with the shared object's symbol to the location specified by the offset.

R_386_GLOB_DAT	This relocation type is used to set a global offset table entry to the address of the specified symbol. The special relocation type allows one to determine the correspondence between symbols and global offset table entries.
R_3862_JMP_SLOT	The link editor creates this relocation type for dynamic linking. Its offset member gives the location of a procedure linkage table entry. The dynamic linker modifies the procedure linkage table entry to transfer control to the designated symbol's address [see "Procedure Linkage Table" in Part 2].
R_386_RELATIVE	The link editor creates this relocation type for dynamic linking. Its offset member gives a location within a shared object that contains a value representing a relative address. The dynamic linker computes the corresponding virtual address by adding the virtual address at which the shared object was loaded to the relative address. Relocation entries for this type must specify 0 for the symbol table index.
R_386_GOTOFF	This relocation type computes the difference between a symbol's value and the address of the global offset table. It additionally instructs the link editor to build the global offset table.
R_386_GOTPC	This relocation type resembles R_386_PC32, except it uses the address of the global offset table in its calculation. The symbol referenced in this relocation normally is _GLOBAL_OFFSET_TABLE_, which additionally instructs the link editor to build the global offset table.

Introduction

Part 2 describes the object file information and system actions that create running programs. Some information here applies to all systems; other information is processor-specific.

Executable and shared object files statically represent programs. To execute such programs, the system uses the files to create dynamic program representations, or process images. A process image has segments that hold its text, data, stack, and so on. The major sections in this part discuss the following.

- *Program header.* This section complements Part 1, describing object file structures that relate directly to program execution. The primary data structure, a program header table, locates segment images within the file and contains other information necessary to create the memory image for the program.
- *Program loading.* Given an object file, the system must load it into memory for the program to run.
- *Dynamic linking.* After the system loads the program, it must complete the process image by resolving symbolic references among the object files that compose the process.

NOTE

There are naming conventions for ELF constants that have specified processor ranges. Names such as `DT_`, `PT_`, for processor-specific extensions, incorporate the name of the processor: `DT_M32_SPECIAL`, for example. Pre-existing processor extensions not using this convention will be supported.

Pre-existing Extensions

`DT_JMP_REL`

Program Header

An executable or shared object file's program header table is an array of structures, each describing a segment or other information the system needs to prepare the program for execution. An object file *segment* contains one or more *sections*, as “Segment Contents” describes below. Program headers are meaningful only for executable and shared object files. A file specifies its own program header size with the ELF header's `e_phentsize` and `e_phnum` members [see “ELF Header” in Part 1].

Figure 2-1: Program Header

```
typedef struct {
    Elf32_Word      p_type;
    Elf32_Off       p_offset;
    Elf32_Addr      p_vaddr;
    Elf32_Addr      p_paddr;
    Elf32_Word      p_filesz;
    Elf32_Word      p_memsz;
    Elf32_Word      p_flags;
    Elf32_Word      p_align;
} Elf32_Phdr;
```

<code>p_type</code>	This member tells what kind of segment this array element describes or how to interpret the array element's information. Type values and their meanings appear below.
<code>p_offset</code>	This member gives the offset from the beginning of the file at which the first byte of the segment resides.
<code>p_vaddr</code>	This member gives the virtual address at which the first byte of the segment resides in memory.
<code>p_paddr</code>	On systems for which physical addressing is relevant, this member is reserved for the segment's physical address. Because System V ignores physical addressing for application programs, this member has unspecified contents for executable files and shared objects.
<code>p_filesz</code>	This member gives the number of bytes in the file image of the segment; it may be zero.
<code>p_memsz</code>	This member gives the number of bytes in the memory image of the segment; it may be zero.
<code>p_flags</code>	This member gives flags relevant to the segment. Defined flag values appear below.
<code>p_align</code>	As “Program Loading” later in this part describes, loadable process segments must have congruent values for <code>p_vaddr</code> and <code>p_offset</code> , modulo the page size. This member gives the value to which the segments are aligned in memory and in the file. Values 0 and 1 mean no alignment is required. Otherwise, <code>p_align</code> should be a positive, integral power of 2, and <code>p_vaddr</code> should equal <code>p_offset</code> , modulo <code>p_align</code> .

Some entries describe process segments; others give supplementary information and do not contribute to the process image. Segment entries may appear in any order, except as explicitly noted below. Defined type values follow; other values are reserved for future use.

Figure 2-2: Segment Types, p_type

Name	Value
PT_NULL	0
PT_LOAD	1
PT_DYNAMIC	2
PT_INTERP	3
PT_NOTE	4
PT_SHLIB	5
PT_PHDR	6
PT_LOPROC	0x70000000
PT_HIPROC	0x7fffffff

PT_NULL	The array element is unused; other members' values are undefined. This type lets the program header table have ignored entries.
PT_LOAD	The array element specifies a loadable segment, described by <code>p_filesz</code> and <code>p_memsz</code> . The bytes from the file are mapped to the beginning of the memory segment. If the segment's memory size (<code>p_memsz</code>) is larger than the file size (<code>p_filesz</code>), the "extra" bytes are defined to hold the value 0 and to follow the segment's initialized area. The file size may not be larger than the memory size. Loadable segment entries in the program header table appear in ascending order, sorted on the <code>p_vaddr</code> member.
PT_DYNAMIC	The array element specifies dynamic linking information. See "Dynamic Section" below for more information.
PT_INTERP	The array element specifies the location and size of a null-terminated path name to invoke as an interpreter. This segment type is meaningful only for executable files (though it may occur for shared objects); it may not occur more than once in a file. If it is present, it must precede any loadable segment entry. See "Program Interpreter" below for further information.
PT_NOTE	The array element specifies the location and size of auxiliary information. See "Note Section" below for details.
PT_SHLIB	This segment type is reserved but has unspecified semantics. Programs that contain an array element of this type do not conform to the ABI.
PT_PHDR	The array element, if present, specifies the location and size of the program header table itself, both in the file and in the memory image of the program. This segment type may not occur more than once in a file. Moreover, it may occur only if the program header table is part of the memory image of the program. If it is present, it must precede any loadable segment entry. See "Program Interpreter" below for further information.
PT_LOPROC through PT_HIPROC	Values in this inclusive range are reserved for processor-specific semantics.

NOTE

Unless specifically required elsewhere, all program header segment types are optional. That is, a file's program header table may contain only those elements relevant to its contents.

Base Address

Executable and shared object files have a *base address*, which is the lowest virtual address associated with the memory image of the program's object file. One use of the base address is to relocate the memory image of the program during dynamic linking.

An executable or shared object file's base address is calculated during execution from three values: the memory load address, the maximum page size, and the lowest virtual address of a program's loadable segment. As "Program Loading" in this chapter describes, the virtual addresses in the program headers might not represent the actual virtual addresses of the program's memory image. To compute the base address, one determines the memory address associated with the lowest `p_vaddr` value for a `PT_LOAD` segment. One then obtains the base address by truncating the memory address to the nearest multiple of the maximum page size. Depending on the kind of file being loaded into memory, the memory address might or might not match the `p_vaddr` values.

As "Sections" in Part 1 describes, the `.bss` section has the type `SHT_NOBITS`. Although it occupies no space in the file, it contributes to the segment's memory image. Normally, these uninitialized data reside at the end of the segment, thereby making `p_memsz` larger than `p_filesz` in the associated program header element.

Note Section

Sometimes a vendor or system builder needs to mark an object file with special information that other programs will check for conformance, compatibility, etc. Sections of type `SHT_NOTE` and program header elements of type `PT_NOTE` can be used for this purpose. The note information in sections and program header elements holds any number of entries, each of which is an array of 4-byte words in the format of the target processor. Labels appear below to help explain note information organization, but they are not part of the specification.

Figure 2-3: Note Information

namesz
descsz

namesz and name

The first **namesz** bytes in **name** contain a null-terminated character representation of the entry's owner or originator. There is no formal mechanism for avoiding name conflicts. By convention, vendors use their own name, such as "XYZ Computer Company," as the identifier. If no name is present, **namesz** contains 0. Padding is present, if necessary, to ensure 4-byte alignment for the descriptor. Such padding is not included in **namesz**.

descsz and desc

The first **descsz** bytes in **desc** hold the note descriptor. The ABI places no constraints on a descriptor's contents. If no descriptor is present, **descsz** contains 0. Padding is present, if necessary, to ensure 4-byte alignment for the next note entry. Such padding is not included in **descsz**.

type

This word gives the interpretation of the descriptor. Each originator controls its own types; multiple interpretations of a single type value may exist. Thus, a program must recognize both the name and the type to "understand" a descriptor. Types currently must be non-negative. The ABI does not define what descriptors mean.

To illustrate, the following note segment holds two entries.

Figure 2-4: Example Note Segment

	+0	+1	+2	+3	
namesz	7				No descriptor
descsz	0				
type	1				
name	X	Y	Z		
	C	o	\0	pad	
namesz	7				
descsz	8				
type	3				
name	X	Y	Z		
	C	o	\0	pad	
desc	word 0				
	word 1				

NOTE

The system reserves note information with no name (**namesz**==0) and with a zero-length name (**name**[0]=='\0') but currently defines no types. All other names must have at least one non-null character.

NOTE

Note information is optional. The presence of note information does not affect a program's ABI conformance, provided the information does not affect the program's execution behavior. Otherwise, the program does not conform to the ABI and has undefined behavior.

Program Loading

As the system creates or augments a process image, it logically copies a file's segment to a virtual memory segment. When—and if—the system physically reads the file depends on the program's execution behavior, system load, etc. A process does not require a physical page unless it references the logical page during execution, and processes commonly leave many pages unreferenced. Therefore delaying physical reads frequently obviates them, improving system performance. To obtain this efficiency in practice, executable and shared object files must have segment images whose file offsets and virtual addresses are congruent, modulo the page size.

Virtual addresses and file offsets for the SYSTEM V architecture segments are congruent modulo 4 KB (0x1000) or larger powers of 2. Because 4 KB is the maximum page size, the files will be suitable for paging regardless of physical page size.

Figure 2-5: Executable File

File Offset	File	Virtual Address
0	ELF header	
Program header table		
	Other information	
0x100	Text segment	0x8048100
	...	
	0x2be00 bytes	0x8073eff
0x2bf00	Data segment	0x8074f00
	...	
	0x4e00 bytes	0x8079cff
0x30d00	Other information	
	...	

Figure 2-6: Program Header Segments

Member	Text	Data
p_type	PT_LOAD	PT_LOAD
p_offset	0x100	0x2bf00
p_vaddr	0x8048100	0x8074f00
p_paddr	unspecified	unspecified
p_filesz	0x2be00	0x4e00
p_memsz	0x2be00	0x5e24
p_flags	PF_R + PF_X	PF_R + PF_W + PF_X
p_align	0x1000	0x1000

Although the example's file offsets and virtual addresses are congruent modulo 4 KB for both text and data, up to four file pages hold impure text or data (depending on page size and file system block size).

- The first text page contains the ELF header, the program header table, and other information.

- The last text page holds a copy of the beginning of data.
- The first data page has a copy of the end of text.
- The last data page may contain file information not relevant to the running process.

Logically, the system enforces the memory permissions as if each segment were complete and separate; segments' addresses are adjusted to ensure each logical page in the address space has a single set of permissions. In the example above, the region of the file holding the end of text and the beginning of data will be mapped twice: at one virtual address for text and at a different virtual address for data.

The end of the data segment requires special handling for uninitialized data, which the system defines to begin with zero values. Thus if a file's last data page includes information not in the logical memory page, the extraneous data must be set to zero, not the unknown contents of the executable file. "Impurities" in the other three pages are not logically part of the process image; whether the system expunges them is unspecified. The memory image for this program follows, assuming 4 KB (0x1000) pages.

Figure 2-7: Process Image Segments

Virtual Address	Contents	Segment
0x8048000	<i>Header padding</i> 0x100 bytes	Text
0x8048100	Text segment ...	
	0x2be00 bytes	
0x8073f00	<i>Data padding</i> 0x100 bytes	
0x8074000	<i>Text padding</i> 0xf00 bytes	Data
0x8074f00	Data segment ...	
	0x4e00 bytes	
0x8079d00	Uninitialized data 0x1024 zero bytes	
0x807ad24	<i>Page padding</i> 0x2dc zero bytes	

One aspect of segment loading differs between executable files and shared objects. Executable file segments typically contain absolute code. To let the process execute correctly, the segments must reside at the virtual addresses used to build the executable file. Thus the system uses the `p_vaddr` values unchanged as virtual addresses.

On the other hand, shared object segments typically contain position-independent code. This lets a segment's virtual address change from one process to another, without invalidating execution behavior. Though the system chooses virtual addresses for individual processes, it maintains the segments' *relative positions*. Because position-independent code uses relative addressing between segments, the difference between virtual addresses in memory must match the difference between virtual addresses in the file. The following table shows possible shared object virtual address assignments for several processes, illustrating constant relative positioning. The table also illustrates the base address computations.

Figure 2-8: Example Shared Object Segment Addresses

Source	Text	Data	Base Address
File	0x200	0x2a400	0x0
Process 1	0x80000200	0x8002a400	0x80000000
Process 2	0x80081200	0x800ab400	0x80081000
Process 3	0x900c0200	0x900ea400	0x900c0000
Process 4	0x900c6200	0x900f0400	0x900c6000

Dynamic Linking

Program Interpreter

An executable file may have one `PT_INTERP` program header element. During `exec(BA_OS)`, the system retrieves a path name from the `PT_INTERP` segment and creates the initial process image from the interpreter file's segments. That is, instead of using the original executable file's segment images, the system composes a memory image for the interpreter. It then is the interpreter's responsibility to receive control from the system and provide an environment for the application program.

The interpreter receives control in one of two ways. First, it may receive a file descriptor to read the executable file, positioned at the beginning. It can use this file descriptor to read and/or map the executable file's segments into memory. Second, depending on the executable file format, the system may load the executable file into memory instead of giving the interpreter an open file descriptor. With the possible exception of the file descriptor, the interpreter's initial process state matches what the executable file would have received. The interpreter itself may not require a second interpreter. An interpreter may be either a shared object or an executable file.

- A shared object (the normal case) is loaded as position-independent, with addresses that may vary from one process to another; the system creates its segments in the dynamic segment area used by `mmap(KE_OS)` and related services. Consequently, a shared object interpreter typically will not conflict with the original executable file's original segment addresses.
- An executable file is loaded at fixed addresses; the system creates its segments using the virtual addresses from the program header table. Consequently, an executable file interpreter's virtual addresses may collide with the first executable file; the interpreter is responsible for resolving conflicts.

Dynamic Linker

When building an executable file that uses dynamic linking, the link editor adds a program header element of type `PT_INTERP` to an executable file, telling the system to invoke the dynamic linker as the program interpreter.

NOTE

The locations of the system provided dynamic linkers are processor-specific.

`Exec(BA_OS)` and the dynamic linker cooperate to create the process image for the program, which entails the following actions:

- Adding the executable file's memory segments to the process image;
- Adding shared object memory segments to the process image;
- Performing relocations for the executable file and its shared objects;
- Closing the file descriptor that was used to read the executable file, if one was given to the dynamic linker;
- Transferring control to the program, making it look as if the program had received control directly from `exec(BA_OS)`.

The link editor also constructs various data that assist the dynamic linker for executable and shared object files. As shown above in “Program Header,” these data reside in loadable segments, making them available during execution. (Once again, recall the exact segment contents are processor-specific. See the processor supplement for complete information.)

- A `.dynamic` section with type `SHT_DYNAMIC` holds various data. The structure residing at the beginning of the section holds the addresses of other dynamic linking information.
- The `.hash` section with type `SHT_HASH` holds a symbol hash table.
- The `.got` and `.plt` sections with type `SHT_PROGBITS` hold two separate tables: the global offset table and the procedure linkage table. Sections below explain how the dynamic linker uses and changes the tables to create memory images for object files.

Because every ABI-conforming program imports the basic system services from a shared object library, the dynamic linker participates in every ABI-conforming program execution.

As “Program Loading” explains in the processor supplement, shared objects may occupy virtual memory addresses that are different from the addresses recorded in the file’s program header table. The dynamic linker relocates the memory image, updating absolute addresses before the application gains control. Although the absolute address values would be correct if the library were loaded at the addresses specified in the program header table, this normally is not the case.

If the process environment [see `exec(BA_OS)`] contains a variable named `LD_BIND_NOW` with a non-null value, the dynamic linker processes all relocation before transferring control to the program. For example, all the following environment entries would specify this behavior.

- `LD_BIND_NOW=1`
- `LD_BIND_NOW=on`
- `LD_BIND_NOW=off`

Otherwise, `LD_BIND_NOW` either does not occur in the environment or has a null value. The dynamic linker is permitted to evaluate procedure linkage table entries lazily, thus avoiding symbol resolution and relocation overhead for functions that are not called. See “Procedure Linkage Table” in this part for more information.

Dynamic Section

If an object file participates in dynamic linking, its program header table will have an element of type `PT_DYNAMIC`. This “segment” contains the `.dynamic` section. A special symbol, `_DYNAMIC`, labels the section, which contains an array of the following structures.

Figure 2-9: Dynamic Structure

```
typedef struct {
    Elf32_Sword    d_tag;
    union {
        Elf32_Word    d_val;
        Elf32_Addr    d_ptr;
    } d_un;
} Elf32_Dyn;

extern Elf32_Dyn_DYNAMIC[];
```

For each object with this type, `d_tag` controls the interpretation of `d_un`.

- `d_val` These `Elf32_Word` objects represent integer values with various interpretations.
- `d_ptr` These `Elf32_Addr` objects represent program virtual addresses. As mentioned previously, a file's virtual addresses might not match the memory virtual addresses during execution. When interpreting addresses contained in the dynamic structure, the dynamic linker computes actual addresses, based on the original file value and the memory base address. For consistency, files do *not* contain relocation entries to "correct" addresses in the dynamic structure.

The following table summarizes the tag requirements for executable and shared object files. If a tag is marked "mandatory," then the dynamic linking array for an ABI-conforming file must have an entry of that type. Likewise, "optional" means an entry for the tag may appear but is not required.

Figure 2-10: Dynamic Array Tags, `d_tag`

Name	Value	d_un	Executable	Shared Object
DT_NULL	0	ignored	mandatory	mandatory
DT_NEEDED	1	d_val	optional	optional
DT_PLTRELSZ	2	d_val	optional	optional
DT_PLTGOT	3	d_ptr	optional	optional
DT_HASH	4	d_ptr	mandatory	mandatory
DT_STRTAB	5	d_ptr	mandatory	mandatory
DT_SYMTAB	6	d_ptr	mandatory	mandatory
DT_RELA	7	d_ptr	mandatory	optional
DT_RELASZ	8	d_val	mandatory	optional
DT_RELAENT	9	d_val	mandatory	optional
DT_STRSZ	10	d_val	mandatory	mandatory
DT_SYMENT	11	d_val	mandatory	mandatory
DT_INIT	12	d_ptr	optional	optional
DT_FINI	13	d_ptr	optional	optional
DT_SONAME	14	d_val	ignored	optional
DT_RPATH	15	d_val	optional	ignored
DT_SYMBOLIC	16	ignored	ignored	optional

Figure 2-10: Dynamic Array Tags, `d_tag` (continued)

Name	Value	<code>d_un</code>	Executable	Shared Object
<code>DT_REL</code>	17	<code>d_ptr</code>	mandatory	optional
<code>DT_RELSZ</code>	18	<code>d_val</code>	mandatory	optional
<code>DT_RELENT</code>	19	<code>d_val</code>	mandatory	optional
<code>DT_PLTREL</code>	20	<code>d_val</code>	optional	optional
<code>DT_DEBUG</code>	21	<code>d_ptr</code>	optional	ignored
<code>DT_TEXTREL</code>	22	ignored	optional	optional
<code>DT_JMPREL</code>	23	<code>d_ptr</code>	optional	optional
<code>DT_LOPROC</code>	0x70000000	unspecified	unspecified	unspecified
<code>DT_HIPROC</code>	0x7fffffff	unspecified	unspecified	unspecified

<code>DT_NULL</code>	An entry with a <code>DT_NULL</code> tag marks the end of the <code>_DYNAMIC</code> array.
<code>DT_NEEDED</code>	This element holds the string table offset of a null-terminated string, giving the name of a needed library. The offset is an index into the table recorded in the <code>DT_STRTAB</code> entry. See “Shared Object Dependencies” for more information about these names. The dynamic array may contain multiple entries with this type. These entries’ relative order is significant, though their relation to entries of other types is not.
<code>DT_PLTRELSZ</code>	This element holds the total size, in bytes, of the relocation entries associated with the procedure linkage table. If an entry of type <code>DT_JMPREL</code> is present, a <code>DT_PLTRELSZ</code> must accompany it.
<code>DT_PLTGOT</code>	This element holds an address associated with the procedure linkage table and/or the global offset table. See this section in the processor supplement for details.
<code>DT_HASH</code>	This element holds the address of the symbol hash table, described in “Hash Table.” This hash table refers to the symbol table referenced by the <code>DT_SYMTAB</code> element.
<code>DT_STRTAB</code>	This element holds the address of the string table, described in Part 1. Symbol names, library names, and other strings reside in this table.
<code>DT_SYMTAB</code>	This element holds the address of the symbol table, described in Part 1, with <code>Elf32_Sym</code> entries for the 32-bit class of files.
<code>DT_RELA</code>	This element holds the address of a relocation table, described in Part 1. Entries in the table have explicit addends, such as <code>Elf32_Rela</code> for the 32-bit file class. An object file may have multiple relocation sections. When building the relocation table for an executable or shared object file, the link editor catenates those sections to form a single table. Although the sections remain independent in the object file, the dynamic linker sees a single table. When the dynamic linker creates the process image for an executable file or adds a shared object to the process image, it reads the relocation table and performs the associated actions. If this element is present, the dynamic structure must also have <code>DT_RELASZ</code> and <code>DT_RELENT</code> elements. When relocation is “mandatory” for a file, either <code>DT_RELA</code> or <code>DT_REL</code> may occur (both are permitted but not required).
<code>DT_RELASZ</code>	This element holds the total size, in bytes, of the <code>DT_RELA</code> relocation table.

<code>DT_RELAENT</code>	This element holds the size, in bytes, of the <code>DT_RELA</code> relocation entry.
<code>DT_STRSZ</code>	This element holds the size, in bytes, of the string table.
<code>DT_SYMENT</code>	This element holds the size, in bytes, of a symbol table entry.
<code>DT_INIT</code>	This element holds the address of the initialization function, discussed in “Initialization and Termination Functions” below.
<code>DT_FINI</code>	This element holds the address of the termination function, discussed in “Initialization and Termination Functions” below.
<code>DT_SONAME</code>	This element holds the string table offset of a null-terminated string, giving the name of the shared object. The offset is an index into the table recorded in the <code>DT_STRTAB</code> entry. See “Shared Object Dependencies” below for more information about these names.
<code>DT_RPATH</code>	This element holds the string table offset of a null-terminated search library search path string, discussed in “Shared Object Dependencies.” The offset is an index into the table recorded in the <code>DT_STRTAB</code> entry.
<code>DT_SYMBOLIC</code>	This element’s presence in a shared object library alters the dynamic linker’s symbol resolution algorithm for references within the library. Instead of starting a symbol search with the executable file, the dynamic linker starts from the shared object itself. If the shared object fails to supply the referenced symbol, the dynamic linker then searches the executable file and other shared objects as usual.
<code>DT_REL</code>	This element is similar to <code>DT_RELA</code> , except its table has implicit addends, such as <code>Elf32_Rel</code> for the 32-bit file class. If this element is present, the dynamic structure must also have <code>DT_RELSZ</code> and <code>DT_RELENT</code> elements.
<code>DT_RELSZ</code>	This element holds the total size, in bytes, of the <code>DT_REL</code> relocation table.
<code>DT_RELENT</code>	This element holds the size, in bytes, of the <code>DT_REL</code> relocation entry.
<code>DT_PLTREL</code>	This member specifies the type of relocation entry to which the procedure linkage table refers. The <code>d_val</code> member holds <code>DT_REL</code> or <code>DT_RELA</code> , as appropriate. All relocations in a procedure linkage table must use the same relocation.
<code>DT_DEBUG</code>	This member is used for debugging. Its contents are not specified for the ABI; programs that access this entry are not ABI-conforming.
<code>DT_TEXTREL</code>	This member’s absence signifies that no relocation entry should cause a modification to a non-writable segment, as specified by the segment permissions in the program header table. If this member is present, one or more relocation entries might request modifications to a non-writable segment, and the dynamic linker can prepare accordingly.
<code>DT_JMPREL</code>	If present, this entry’s <code>d_ptr</code> member holds the address of relocation entries associated solely with the procedure linkage table. Separating these relocation entries lets the dynamic linker ignore them during process initialization, if lazy binding is enabled. If this entry is present, the related entries of types <code>DT_PLTRELSZ</code> and <code>DT_PLTREL</code> must also be present.
<code>DT_LOPROC</code> through <code>DT_HIPROC</code>	Values in this inclusive range are reserved for processor-specific semantics.

Except for the `DT_NULL` element at the end of the array, and the relative order of `DT_NEEDED` elements, entries may appear in any order. Tag values not appearing in the table are reserved.

Shared Object Dependencies

When the link editor processes an archive library, it extracts library members and copies them into the output object file. These statically linked services are available during execution without involving the dynamic linker. Shared objects also provide services, and the dynamic linker must attach the proper shared object files to the process image for execution. Thus executable and shared object files describe their specific dependencies.

When the dynamic linker creates the memory segments for an object file, the dependencies (recorded in `DT_NEEDED` entries of the dynamic structure) tell what shared objects are needed to supply the program's services. By repeatedly connecting referenced shared objects and their dependencies, the dynamic linker builds a complete process image. When resolving symbolic references, the dynamic linker examines the symbol tables with a breadth-first search. That is, it first looks at the symbol table of the executable program itself, then at the symbol tables of the `DT_NEEDED` entries (in order), then at the second level `DT_NEEDED` entries, and so on. Shared object files must be readable by the process; other permissions are not required.

NOTE

Even when a shared object is referenced multiple times in the dependency list, the dynamic linker will connect the object only once to the process.

Names in the dependency list are copies either of the `DT_SONAME` strings or the path names of the shared objects used to build the object file. For example, if the link editor builds an executable file using one shared object with a `DT_SONAME` entry of `lib1` and another shared object library with the path name `/usr/lib/lib2`, the executable file will contain `lib1` and `/usr/lib/lib2` in its dependency list.

If a shared object name has one or more slash (/) characters anywhere in the name, such as `/usr/lib/lib2` above or `directory/file`, the dynamic linker uses that string directly as the path name. If the name has no slashes, such as `lib1` above, three facilities specify shared object path searching, with the following precedence.

- First, the dynamic array tag `DT_RPATH` may give a string that holds a list of directories, separated by colons (:). For example, the string `/home/dir/lib:/home/dir2/lib:` tells the dynamic linker to search first the directory `/home/dir/lib`, then `/home/dir2/lib`, and then the current directory to find dependencies.
- Second, a variable called `LD_LIBRARY_PATH` in the process environment [see `exec(BA_OS)`] may hold a list of directories as above, optionally followed by a semicolon (;) and another directory list. The following values would be equivalent to the previous example:
 - `LD_LIBRARY_PATH=/home/dir/lib:/home/dir2/lib:`
 - `LD_LIBRARY_PATH=/home/dir/lib;/home/dir2/lib:`
 - `LD_LIBRARY_PATH=/home/dir/lib:/home/dir2/lib;;`

All `LD_LIBRARY_PATH` directories are searched after those from `DT_RPATH`. Although some programs (such as the link editor) treat the lists before and after the semicolon differently, the dynamic linker does not. Nevertheless, the dynamic linker accepts the semicolon notation, with the

semantics described above.

- Finally, if the other two groups of directories fail to locate the desired library, the dynamic linker searches `/usr/lib`.

NOTE

For security, the dynamic linker ignores environmental search specifications (such as `LD_LIBRARY_PATH`) for set-user and set-group ID programs. It does, however, search `DT_RPATH` directories and `/usr/lib`.

Global Offset Table

Position-independent code cannot, in general, contain absolute virtual addresses. Global offset tables hold absolute addresses in private data, thus making the addresses available without compromising the position-independence and sharability of a program's text. A program references its global offset table using position-independent addressing and extracts absolute values, thus redirecting position-independent references to absolute locations.

Initially, the global offset table holds information as required by its relocation entries [see "Relocation" in Part 1]. After the system creates memory segments for a loadable object file, the dynamic linker processes the relocation entries, some of which will be type `R_386_GLOB_DAT` referring to the global offset table. The dynamic linker determines the associated symbol values, calculates their absolute addresses, and sets the appropriate memory table entries to the proper values. Although the absolute addresses are unknown when the link editor builds an object file, the dynamic linker knows the addresses of all memory segments and can thus calculate the absolute addresses of the symbols contained therein.

If a program requires direct access to the absolute address of a symbol, that symbol will have a global offset table entry. Because the executable file and shared objects have separate global offset tables, a symbol's address may appear in several tables. The dynamic linker processes all the global offset table relocations before giving control to any code in the process image, thus ensuring the absolute addresses are available during execution.

The table's entry zero is reserved to hold the address of the dynamic structure, referenced with the symbol `_DYNAMIC`. This allows a program, such as the dynamic linker, to find its own dynamic structure without having yet processed its relocation entries. This is especially important for the dynamic linker, because it must initialize itself without relying on other programs to relocate its memory image. On the 32-bit Intel Architecture, entries one and two in the global offset table also are reserved. "Procedure Linkage Table" below describes them.

The system may choose different memory segment addresses for the same shared object in different programs; it may even choose different library addresses for different executions of the same program. Nonetheless, memory segments do not change addresses once the process image is established. As long as a process exists, its memory segments reside at fixed virtual addresses.

A global offset table's format and interpretation are processor-specific. For the 32-bit Intel Architecture, the symbol `_GLOBAL_OFFSET_TABLE_` may be used to access the table.

Figure 2-11: Global Offset Table

```
extern Elf32_Addr      _GLOBAL_OFFSET_TABLE_[];
```

The symbol `_GLOBAL_OFFSET_TABLE_` may reside in the middle of the `.got` section, allowing both negative and non-negative “subscripts” into the array of addresses.

Procedure Linkage Table

Much as the global offset table redirects position-independent address calculations to absolute locations, the procedure linkage table redirects position-independent function calls to absolute locations. The link editor cannot resolve execution transfers (such as function calls) from one executable or shared object to another. Consequently, the link editor arranges to have the program transfer control to entries in the procedure linkage table. On the SYSTEM V architecture, procedure linkage tables reside in shared text, but they use addresses in the private global offset table. The dynamic linker determines the destinations’ absolute addresses and modifies the global offset table’s memory image accordingly. The dynamic linker thus can redirect the entries without compromising the position-independence and sharability of the program’s text. Executable files and shared object files have separate procedure linkage tables.

Figure 2-12: Absolute Procedure Linkage Table

```
.PLT0:pushl got_plus_4
      jmp   *got_plus_8
      nop; nop
      nop; nop
.PLT1: jmp   *name1_in_GOT
      pushl $offset@PC
.PLT2: jmp   *name2_in_GOT
      push  $offset
      jmp   .PLT0@PC
      ...
```

Figure 2-13: Position-Independent Procedure Linkage Table

```

.PLT0: pushl 4(%ebx)
      jmp  *8(%ebx)
      nop; nop
      nop; nop
.PLT1: jmp  *name1@GOT(%ebx)
      pushl $offset
      jmp  .PLT0@PC
.PLT2: jmp  *name2@GOT(%ebx)
      pushl $offset
      jmp  .PLT0@PC
      ...

```

NOTE

As the figures show, the procedure linkage table instructions use different operand addressing modes for absolute code and for position-independent code. Nonetheless, their interfaces to the dynamic linker are the same.

Following the steps below, the dynamic linker and the program “cooperate” to resolve symbolic references through the procedure linkage table and the global offset table.

1. When first creating the memory image of the program, the dynamic linker sets the second and the third entries in the global offset table to special values. Steps below explain more about these values.
2. If the procedure linkage table is position-independent, the address of the global offset table must reside in `%ebx`. Each shared object file in the process image has its own procedure linkage table, and control transfers to a procedure linkage table entry only from within the same object file. Consequently, the calling function is responsible for setting the global offset table base register before calling the procedure linkage table entry.
3. For illustration, assume the program calls `name1`, which transfers control to the label `.PLT1`.
4. The first instruction jumps to the address in the global offset table entry for `name1`. Initially, the global offset table holds the address of the following `pushl` instruction, not the real address of `name1`.
5. Consequently, the program pushes a relocation offset (*offset*) on the stack. The relocation offset is a 32-bit, non-negative byte offset into the relocation table. The designated relocation entry will have type `R_386_JMP_SLOT`, and its offset will specify the global offset table entry used in the previous `jmp` instruction. The relocation entry also contains a symbol table index, thus telling the dynamic linker what symbol is being referenced, `name1` in this case.
6. After pushing the relocation offset, the program then jumps to `.PLT0`, the first entry in the procedure linkage table. The `pushl` instruction places the value of the second global offset table entry (*got_plus_4* or `4(%ebx)`) on the stack, thus giving the dynamic linker one word of identifying information. The program then jumps to the address in the third global offset table entry

(*got_plus_8* or `8(%ebx)`), which transfers control to the dynamic linker.

7. When the dynamic linker receives control, it unwinds the stack, looks at the designated relocation entry, finds the symbol's value, stores the "real" address for `name1` in its global offset table entry, and transfers control to the desired destination.
8. Subsequent executions of the procedure linkage table entry will transfer directly to `name1`, without calling the dynamic linker a second time. That is, the `jmp` instruction at `.PLT1` will transfer to `name1`, instead of "falling through" to the `pushl` instruction.

The `LD_BIND_NOW` environment variable can change dynamic linking behavior. If its value is non-null, the dynamic linker evaluates procedure linkage table entries before transferring control to the program. That is, the dynamic linker processes relocation entries of type `R_386_JMP_SLOT` during process initialization. Otherwise, the dynamic linker evaluates procedure linkage table entries lazily, delaying symbol resolution and relocation until the first execution of a table entry.

NOTE

Lazy binding generally improves overall application performance, because unused symbols do not incur the dynamic linking overhead. Nevertheless, two situations make lazy binding undesirable for some applications. First, the initial reference to a shared object function takes longer than subsequent calls, because the dynamic linker intercepts the call to resolve the symbol. Some applications cannot tolerate this unpredictability. Second, if an error occurs and the dynamic linker cannot resolve the symbol, the dynamic linker will terminate the program. Under lazy binding, this might occur at arbitrary times. Once again, some applications cannot tolerate this unpredictability. By turning off lazy binding, the dynamic linker forces the failure to occur during process initialization, before the application receives control.

Hash Table

A hash table of `Elf32_Word` objects supports symbol table access. Labels appear below to help explain the hash table organization, but they are not part of the specification.

Figure 2-14: Symbol Hash Table

<code>nbucket</code>
<code>nchain</code>
<code>bucket[0]</code>
<code>. . .</code>
<code>bucket[nbucket - 1]</code>
<code>chain[0]</code>
<code>. . .</code>
<code>chain[nchain - 1]</code>

The `bucket` array contains `nbucket` entries, and the `chain` array contains `nchain` entries; indexes start at 0. Both `bucket` and `chain` hold symbol table indexes. Chain table entries parallel the symbol table. The number of symbol table entries should equal `nchain`; so symbol table indexes also select chain table entries. A hashing function (shown below) accepts a symbol name and returns a value that may be used to compute a bucket index. Consequently, if the hashing function returns the value x for some name, `bucket[x%nbucket]` gives an index, y , into both the symbol table and the chain table. If the symbol table entry is not the one desired, `chain[y]` gives the next symbol table entry with the same hash value. One can follow the `chain` links until either the selected symbol table entry holds the desired

name or the chain entry contains the value `STN_UNDEF`.

Figure 2-15: Hashing Function

```
unsigned long
elf_hash(const unsigned char *name)
{
    unsigned long    h = 0, g;

    while (*name)
    {
        h = (h << 4) + *name++;
        if (g = h & 0xf0000000)
            h ^= g >> 24;
        h &= ~g;
    }
    return h;
}
```

Initialization and Termination Functions

After the dynamic linker has built the process image and performed the relocations, each shared object gets the opportunity to execute some initialization code. These initialization functions are called in no specified order, but all shared object initializations happen before the executable file gains control.

Similarly, shared objects may have termination functions, which are executed with the `atexit(BA_OS)` mechanism after the base process begins its termination sequence. Once again, the order in which the dynamic linker calls termination functions is unspecified.

Shared objects designate their initialization and termination functions through the `DT_INIT` and `DT_FINI` entries in the dynamic structure, described in “Dynamic Section” above. Typically, the code for these functions resides in the `.init` and `.fini` sections, mentioned in “Sections” of Part 1.

NOTE

Although the `atexit(BA_OS)` termination processing normally will be done, it is not guaranteed to have executed upon process death. In particular, the process will not execute the termination processing if it calls `_exit` [see `exit(BA_OS)`] or if the process dies because it received a signal that it neither caught nor ignored.

3 C LIBRARY

C Library	3-1
Global Data Symbols	3-2

C Library

The C library, `libc`, contains all of the symbols contained in `libsys`, and, in addition, contains the routines listed in the following two tables. The first table lists routines from the ANSI C standard.

Figure 3-1: `libc` Contents, Names without Synonyms

<code>abort</code>	<code>fputc</code>	<code>isprint</code>	<code>putc</code>	<code>strncmp</code>
<code>abs</code>	<code>fputs</code>	<code>ispunct</code>	<code>putchar</code>	<code>strncpy</code>
<code>asctime</code>	<code>fread</code>	<code>isspace</code>	<code>puts</code>	<code>strpbrk</code>
<code>atof</code>	<code>freopen</code>	<code>isupper</code>	<code>qsort</code>	<code>strrchr</code>
<code>atoi</code>	<code>frexp</code>	<code>isxdigit</code>	<code>raise</code>	<code>strspn</code>
<code>atol</code>	<code>fscanf</code>	<code>labs</code>	<code>rand</code>	<code>strstr</code>
<code>bsearch</code>	<code>fseek</code>	<code>ldexp</code>	<code>rewind</code>	<code>strtod</code>
<code>clearerr</code>	<code>fsetpos</code>	<code>ldiv</code>	<code>scanf</code>	<code>strtok</code>
<code>clock</code>	<code>ftell</code>	<code>localtime</code>	<code>setbuf</code>	<code>strtol</code>
<code>ctime</code>	<code>fwrite</code>	<code>longjmp</code>	<code>setjmp</code>	<code>strtoul</code>
<code>difftime</code>	<code>getc</code>	<code>mblen</code>	<code>setvbuf</code>	<code>tmpfile</code>
<code>div</code>	<code>getchar</code>	<code>mbstowcs</code>	<code>sprintf</code>	<code>tmpnam</code>
<code>fclose</code>	<code>getenv</code>	<code>mbtowc</code>	<code>srand</code>	<code>tolower</code>
<code>feof</code>	<code>gets</code>	<code>memchr</code>	<code>sscanf</code>	<code>toupper</code>
<code>ferror</code>	<code>gmtime</code>	<code>memcmp</code>	<code>strcat</code>	<code>ungetc</code>
<code>fflush</code>	<code>isalnum</code>	<code>memcpy</code>	<code>strchr</code>	<code>vfprintf</code>
<code>fgetc</code>	<code>isalpha</code>	<code>memmove</code>	<code>strcmp</code>	<code>vprintf</code>
<code>fgetpos</code>	<code>iscntrl</code>	<code>memset</code>	<code>strcpy</code>	<code>vsprintf</code>
<code>fgets</code>	<code>isdigit</code>	<code>mktime</code>	<code>strcspn</code>	<code>wcstombs</code>
<code>fopen</code>	<code>isgraph</code>	<code>perror</code>	<code>strlen</code>	<code>wctomb</code>
<code>fprintf</code>	<code>islower</code>	<code>printf</code>	<code>strncat</code>	

Additionally, `libc` holds the following services.

Figure 3-2: `libc` Contents, Names with Synonyms

<code>__assert</code>	<code>getdate</code>	<code>lockf</code> †	<code>sleep</code>	<code>tell</code> †
<code>cfgetispeed</code>	<code>getopt</code>	<code>lsearch</code>	<code>strdup</code>	<code>tempnam</code>
<code>cfgetospeed</code>	<code>getpass</code>	<code>memccpy</code>	<code>swab</code>	<code>tfind</code>
<code>cfsetispeed</code>	<code>getsubopt</code>	<code>mkfifo</code>	<code>tcdrain</code>	<code>toascii</code>
<code>cfsetospeed</code>	<code>getw</code>	<code>mktemp</code>	<code>tcflow</code>	<code>_tolower</code>
<code>ctermid</code>	<code>hcreate</code>	<code>monitor</code>	<code>tcflush</code>	<code>tsearch</code>
<code>cuserid</code>	<code>hdestroy</code>	<code>nftw</code>	<code>tcgetattr</code>	<code>_toupper</code>
<code>dup2</code>	<code>hsearch</code>	<code>nl_langinfo</code>	<code>tcgetpgrp</code>	<code>twalk</code>
<code>fdopen</code>	<code>isascii</code>	<code>pclose</code>	<code>tcgetsid</code>	<code>tzset</code>
<code>__filbuf</code>	<code>isatty</code>	<code>popen</code>	<code>tcsendbreak</code>	<code>_xftw</code>
<code>fileno</code>	<code>isnan</code>	<code>putenv</code>	<code>tcsetattr</code>	
<code>__flsbuf</code>	<code>isnand</code> †	<code>putw</code>	<code>tcsetpgrp</code>	
<code>fmsg</code> †	<code>lfind</code>	<code>setlabel</code>	<code>tdelete</code>	

† Function is at Level 2 in the SVID Issue 3 and therefore at Level 2 in the ABI.

Besides the symbols listed in the With Synonyms table above, synonyms of the form `_name` exist for *name* entries that are not listed with a leading underscore prepended to their name. Thus `libc` contains both `getopt` and `_getopt`, for example.

Of the routines listed above, the following are not defined elsewhere.

```
int __filbuf(FILE *f);
    This function returns the next input character for f, filling its buffer as appropriate. It
    returns EOF if an error occurs.

int __flsbuf(int x, FILE *f);
    This function flushes the output characters for f as if putc(x,f) had been called and then
    appends the value of x to the resulting output stream. It returns EOF if an error occurs and
    x otherwise.

int _xftw(int, char *, int (*)(char *, struct stat *, int), int);
    Calls to the ftw(BA_LIB) function are mapped to this function when applications are com-
    piled. This function is identical to ftw(BA_LIB), except that _xftw() takes an interposed
    first argument, which must have the value 2.
```

See this chapter’s other library sections for more SVID, ANSI C, and POSIX facilities. See “System Data Interfaces” later in this chapter for more information.

Global Data Symbols

The `libc` library requires that some global external data symbols be defined for its routines to work properly. All the data symbols required for the `libsys` library must be provided by `libc`, as well as the data symbols listed in the table below.

For formal declarations of the data objects represented by these symbols, see the *System V Interface Definition, Third Edition* or the “Data Definitions” section of Chapter 6 in the appropriate processor supplement to the *System V ABI*.

For entries in the following table that are in *name* - *_name* form, both symbols in each pair represent the same data. The underscore synonyms are provided to satisfy the ANSI C standard.
